(54) Bidirectionally stretchable support tape for hook-and-loop fasteners.

(57) A support tape (10) for hook-and-loop fastener is composed of a bidirectionally stretchable weft-knit web (10a) formed of a combination of an elastic foundation yarn (14) and a non-elastic pile yarn (15) concurrently interlooped together, and an elastic material layer coated on the underside of the weft-knit web.

FIG. 1

EP 0 233 364 A2

BIDIRECTIONALLY STRETCHABLE SUPPORT TAPE FOR HOOK-AND-LOOP FASTENERS

This invention relates to a surface-type fastener generally known as a hook-and-loop fastener, and more particularly to a stretchable support tape for such hook-and-loop fasteners suitable for use on, for example, a health or sporting belt or band.

A typical stretchable support tape for hook-and-loop fasteners is known as disclosed for example in Japanese Patent Publication 55-38121. The disclosed support tape, as reillustrated here in Figure 3 is formed by weaving and includes pile loops A produced from loop-forming warp threads interwoven with a foundation weft thread, and elastic yarns B woven into the tape to render the tape stretchable. Since such a support tape is a relatively narrow fabric produced by weaving on a complex machine, there have been problems of low production efficiency.

The present invention seeks to provide a stretchable support tape for hook-and-loop fasteners, which can be manufactured efficiently at a high rate of production.

The present invention further seeks to provide a support tape for hook-and-loop fasteners, which has a knit structure stretchable in both longitudinal and transverse directions.

The present invention further seeks to provide a support tape for hook-and-loop fasteners, which can be made with varied densities of loops.

The foregoing and other objects of the present invention are attained by a support tape for hook-and-loop fasteners, comprising: a bidirectionally stretchable weft-knit web having a plain stitch construction formed of an elastic foundation yarn and a non-elastic pile yarn concurrently looped together; and a layer of an elastic material coated on the underside of said weft-knit web.

Many other advantages and features of the present invention will become manifest to those versed in the art upon making reference to the detailed description and the accompanying sheets of drawings in which preferred structural embodiments incorporating the principles of the present invention are shown by way of illustrative example.

Figure 1 is a schematic diagram illustrating the construction of a support tape for a hook-and-loop fastener embodying the present invention;

Figure 2 is a schematic end view of the support tape shown in Figure 1;

Figure 3 is a view similar to Figure 1 but illustrating a modified form of the support tape; and

Figure 4, appearing with Figure 2, is a schematic illustration on enlarged scale of a known support tape of a woven structure.

Referring now to the drawings and Figure 1 in particular, there is shown a support tape 10 for use as a female part of a hook-and-loop fastener releasably engageable with a male part thereof. The tape 10 is made up of a weft-knit web 10a knitted on a latch needle plain fabric circular knitting machine, into a cylindrical form which is then cut along its longitudinal axis and spread out into the illustrated sheet form. The knitting machine includes high sinkers and normal or low sinkers for a purpose described below.

The weft-knit tape web 10a is composed of a pile portion 11 and selvage portions 12 and 13 extending on opposite sides of the pile portion 11. The selvage portions 12, 13 may of course be replaced by the pile portion 11 depending upon a purpose for which the tape 10 is used. The pile portion 11 and the selvage portion 12, 13 as well are formed by a combination of a foundation yarn 14 and a pile yarn 15 concurrently interlooped as a plain stitch construction on the knitting machine, in which instance the high sinkers are utilized to form pile loops 15a in the pile portion 11 from the pile yarn 15 whereas the low sinkers are utilized for formation of the selvage portions 12, 13.

The foundation yarn 14 is an elastic yarn such as spandex covered yarn, or crimped yarn or like textured yarn, while the pile yarn 15 is a non-elastic yarn such as a multifilament yarn of nylon or polyester, or monofilament yarn of nylon or polyester. Thus, during the knitting operation, the elastic foundation yarn 14 is fed under stretched condition, so as to be contracted after the weft-knit web 10a has been removed from the knitting machine. Since the length of the non-elastic pile yarn 15 does not vary, there results in an excessive length relative to the shrunk foundation yarn, particularly in the pile portion 11 of the weft-knit web 10a where the high sinkers are used. This excessive length of the non-elastic pile yarn 15 serves to form the loops 15a which project from a front surface of the weft-knit web 10a. The weft-knit web 10a thus produced is stretchable in both longitudinal and transverse directions. The stretchability or elasticity in the longitudinal direction is obtained mainly due to the elasticity of the foundation yarn 14, while the elasticity in the transverse direction is obtained by the combination of the elastic foundation yarn 14 and the intrinsic elasticity of the weft-knit structure itself.

In the case where the pile loops 15a are formed by a multifilament yarn, they may be brushed into a multiplicity of fan-up loops so as to provide an enhanced engageability with hooks on a companion male fastener tape not shown.

As shown in Figure 2, the resulting weft-knit tape web 10a is then coated or laminated on its the back face with a layer 10b of a synthetic rubber, polyurethane resin or other elastic binder material so as to retain the pile loops 15a in place against unintentional removal and to maintain bidirectional stretchability of the tape 10 as a whole.

Figure 3 shows a modified support tape 30 according to the invention which is characterized by changing loop densities in a weft-knit web 30a of the tape 30 or varied numbers of pile loops distributed per unit area of the tape web 30a. This weft-knit tape web 30a has a group of pile loops 31 skipped every other wale and course and hence less densely distributed compared to the tape web 10a of Figure 1, as this is readily made possible by adjusted arrangement and operation of the sinkers. The loop density may be varied also for the longitudinal or transverse direction above. When it is desired to vary the loop density only transversely or coursewise of the tape web 30a, this can be conveniently done by replacing the pile yarn 32 and the foundation yarn 33 of selected courses - (every other course in Figure 3) with another foundation yarn 34 as shown, in which instance the foundation yarn 34 should be thicker than the elastic foundation yarn 33 so as to compensate for the size and strength of knit mesh lost by the absence of pile yarn 32.

When a support tape for a male or hook fastener member is to be manufactured, the loop-forming multifilament pile yarn 15, 32 of the weft-knit web 10a, 30a of the foregoing embodiments should be replaced with a monofilament yarn of nylon or polyester. Loops formed of the monofilament yarn are then cut on their one side to form hooks. Alternatively, the loops may be cut on their top to form pairs of hooks which are then shaped by melting into mushroom-shaped interlocking elements. Likewise the weft-knit webs 10a, 30a, the weft-knit web is coated with a layer of elastic material.

As described above, the support tape of the present invention is stretchable in both longitudinal and transverse directions, therefore when used as a tape for hook-and-loop fasteners, the support tape will provide an enhanced engageability with a mating tape. With this enhanced engageability, the hook-and-loop fastener having such support tape is particularly suitable for use on, for example, a health or sporting belt or band. Since the weft-knit tape web has a plain stitch construction, it can easily be produced at a higher rate of production than the conventional woven support tape, and also can be made with varied densities of loops. Furthermore, with the coated layer of elastic material, the bidirectional stretchability of the support tape is provided for a long period of time.

Claims

1. A support tape (10; 30) for hook-and-loop fasteners, comprising:

(a) a bidirectionally stretchable weft-knit web (10a; 30a) having a plain stitch construction formed of an elastic foundation yarn (14; 33) and a non-elastic pile yarn (15; 32) concurrently looped together; and

(b) a layer (10b) of an elastic material coated on the underside of said weft-knit web (10a; 30a).

2. A support tape according to claim 1, said elastic foundation yarn (14) comprising a spandex covered yarn.

3. A support tape according to claim 1, said elastic foundation yarn (14) comprising a crimped yarn.

4. A support tape according to claim 1, said elastic material layer (10b) being formed of a synthetic rubber.

5. A support tape according to claim 1, said elastic material layer (10b) being formed of an urethane resin.

6. A support tape according to claim 1, further including a foundation yarn (34) extending solely between selected pairs of adjacent courses and interknitted with said weft-knit web (30) and inter-looped with said elastic foundation yarn (32) and said pile yarn (33) in said selected pairs of courses.

7. A support tape according to claim 4, said last-named foundation yarn (34) being thicker than said elastic foundation yarn (33).
